Tobias University of Birmingham, England INTRODUCTION The machining of metals and other materials is invariably accompanied by relative vibration between workpiece and tool. Virtual inertias for pumps and the like are not known accurately but can be assumed as if half the casing were filled with rotating fluid.

This can be shown by applying the method previously used in the cases of drilling and face milling to the problem of lathe chatter under orflloqonol cutting conditions. Hence the effective width of face of the pinion and gear will be If inches.

BALANCING OF ROTATING PARTS PRODUCTION BALANCING MACHINES Balancing machines used for balancing work during production fall into three general classes; 1 the universal balancing machine, 2 the semiautomatic balancing machine, and 3 the fully automatic balancing machine with automatic transfer of work. Indeed, if history is the story that scientific cultures tell about themselves, then the story apparently does its work by simultaneously empowering writing and rendering it transparent. Better results may be obtained at lower speeds.
